

Simple Notification Service (SNS)

Subscribe and **send notifications** via
text message email, webhooks, lambdas, SQS and mobile notifications

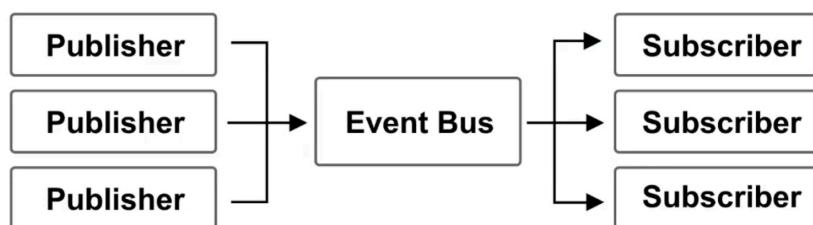

Introduction to SNS

What is Pub/Sub?

Publish–subscribe pattern commonly implemented in **messaging systems**. In a pub/sub system the sender of messages (**publishers**) do not send their messages directly to receivers. They instead send their messages to an **event bus**. The event bus categorizes their messages into groups. Then receivers of messages (**subscribers**) subscribe to these groups. Whenever new messages appear within their subscription the messages are immediately delivered to them.

- Publisher have no knowledge of who their subscribers are.
- Subscribers do **not pull** for messages.
- Messages are instead automatically and immediately **pushed** to subscribers.
- Messages and events are interchangeable terms in pub/sub

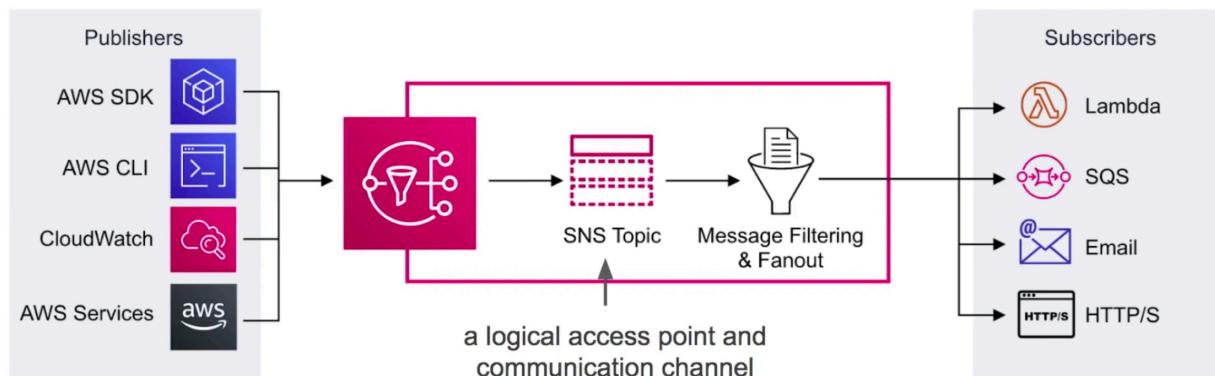

Introduction to SNS

Simple Notification Service (SNS) is a highly available, durable, secure, fully managed **pub/sub messaging** service that enables you to **decouple** microservices, distributed systems, and serverless applications.

Application Integration!

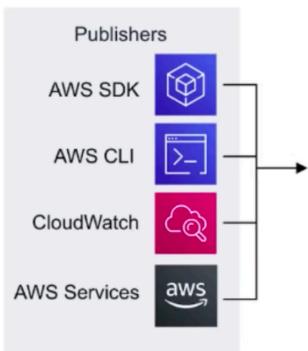

- Publishers **push** events to an SNS Topic
- Subscribers subscribe to SNS Topic to have events **pushed** to them

SNS - Topics

Publishers don't care about the subscribers protocol

Topics allow you to group multiple subscriptions together.

A topic is able to deliver to multiple protocols at once eg. email, text message, http/s

When topics deliver messages to subscribers it will automatically format your message according to the subscriber's chosen protocol

You can encrypt Topics via KMS

Encryption

Enable encryption [Learn more](#)

Enabling server side encryption adds at-rest encryption to your topic. Amazon SNS encrypts your message as soon as it is received. The message is decrypted immediately prior to delivery.

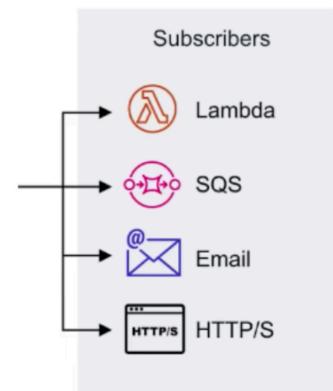

Disable encryption

Customer master key (CMK)

Select a custom CMK or enter an existing CMK ARN.

(Default) alias/aws/sns

Subscribers listen for incoming messages

SNS - Subscriptions

Subscriptions (1)

| ID | Endpoint | Status | Protocol |
|--------------------------------------|-------------------|-----------|----------|
| 33d3e87b-413e-412a-bca3-32b2b14cb24d | andrew@exampro.co | Confirmed | EMAIL |

Create subscription

To receive messages from a topic you need to create a Subscription.

A subscription can only subscribe to one protocol and one topic.

The following protocols:

HTTPs and HTTPs create webhooks into your web-application
Email good for internal email notifications (only supports **plain text**)

Email-JSON sends you json via email

Amazon SQS place SNS message into SQS queue

AWS Lambda triggers a lambda function

SMS send a text message

Platform application endpoints Mobile Push

Protocol

The type of endpoint to subscribe

Select protocol

HTTP

HTTPS

Email

Email-JSON

Amazon SQS

AWS Lambda

Platform application endpoint

SMS

Application As Subscriber

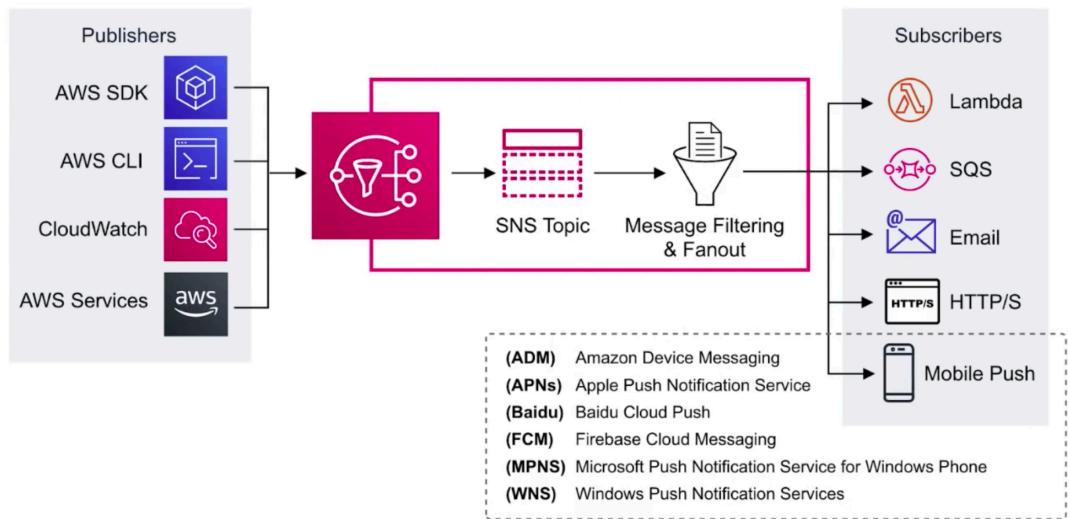

Send push notification messages directly to apps on **mobile devices**.

Push notification messages sent to a mobile endpoint can appear in the mobile app as message alerts, badge updates, or even sound alerts.

Protocol
The type of endpoint to subscribe

Select protocol

- HTTP
- HTTPS
- Email
- Email-JSON
- Amazon SQS
- AWS Lambda
- Platform application endpoint**
- SMS

SNS *CheatSheet*

- **Simple Notification Service (SNS)** is a fully managed pub/sub messaging service
- SNS is for **Application Integration**. It allows decoupled services and apps to communicate with each other
- **Topic** a logical access point and communication channel.
- A topic is able to deliver to multiple protocols
- You can encrypt topics via KMS
- **Publishers** use the AWS API via AWS CLI or SDK to push messages to a topic. Many AWS services integrate with SNS and act as publishers.
- **Subscriptions** subscribe to topics. When a topic receives a message it automatically and immediately pushes messages to subscribers.
- All messages published to SNS are stored redundantly across multiple Availability Zones (AZ)
- The following protocols:
 - **HTTPs and HTTPS** create webhooks into your web-application
 - **Email** good for internal email notifications (only supports **plain text**)
 - **Email-JSON** sends you json via email
 - **Amazon SQS** place SNS message into SQS queue
 - **AWS Lambda** triggers a lambda function
 - **SMS** send a text message
 - **Platform application endpoints** Mobile Push eg. Apple, Google, Microsoft Baidu notification systems
